Data Preprocessing Steps

Handling Delimiters

- Step 1:** Converting Commas to Semicolons in the Dataset
Objective: Ensure the dataset is properly formatted by replacing all semicolons (;) with commas (,).

- Step 2:** Clean the "Country" Column Data **Objective:** Ensure data quality by addressing issues with special characters. In our database, we found that the value "Cote d'Ivoire" in the "Country" column contains an apostrophe, which is causing an error in the Wiki.

Problem: The value "Cote d'Ivoire" includes an apostrophe that leads to errors during data analysis or query execution.

- Step 3:** Re-encoding the "Order Priority" Column We performed re-encoding of the textual values in the "Order Priority" column into numerical values to facilitate processing by machine learning algorithms.

The values were transformed as follows:

Critical → 3
High → 2
Medium → 1
Low → 0

This step was necessary because some algorithms, such as Naïve Bayes and K-Means, require numerical data for analysis and processing.

Algorithm Implementation

Apriori Algorithm (Association Rule Mining)

- **Objective:** Discover frequent itemsets and generate association rules.
- **Selected Columns:** Item Type, Sales Channel.
- **Parameters:**
 - Support Threshold: A reasonable value based on dataset characteristics.
 - Confidence Threshold: Set a meaningful value to filter rules.
 - Lift: Evaluated to assess rule significance.
- **Steps:**
 - Preprocessed data by removing duplicates and inconsistencies.
 - Implemented Apriori using association rule mining tools in Weka.

Step 1: Association Rule Mining (Apriori)

Business Insights

Key Insight: When frozenset(['Region_Australia and Oceania']), they are 75.0% likely to also frozenset(['Order Priority']) (Lift = 1.00)

Algorithm and Reasoning:

The Apriori algorithm is used to identify frequent itemsets in a dataset and generate association rules. It helps in discovering interesting relationships between variables in large databases.

Parameters:

- **Support Threshold:** A minimum percentage of records in the dataset that contain the itemset. In our case, with 10,000 records, a support threshold of 0.05 means any itemset must appear in at least 500 transactions to be considered significant.
- **Confidence Threshold:** The likelihood that a rule is true for the dataset. A threshold of 0.5 means we are interested in rules where the likelihood is at least 50%.
- **Lift:** Measures the importance of a rule. $\text{Lift} > 1$ indicates a strong association.

Naïve Bayes (Classification)

- **Objective:** Build a probabilistic model to classify data into predefined classes.
- **Selected Columns:** Region, Country, Item Type, Sales Channel, Order Priority.
- **Steps:**
 - Split dataset into training (70%) and testing (30%) sets.
 - Assumed feature independence.
 - Evaluated model using accuracy, precision, recall, and F1-score.

Naïve Bayes is a probabilistic classification algorithm based on Bayes' Theorem. It assumes that the presence of a particular feature in a class is unrelated to the presence of any other feature.

- **Region:** Useful for understanding geographic influence on purchasing behavior.
- **Country:** To identify differences between countries.
- **Item Type:** To know the types of products that are bought together.
- **Sales Channel:** To understand the differences between various sales channels (online and offline).
- **Order Priority:** To understand how order priority affects product relationships.

- **Objective:** Create decision trees based on information gain.
- **Selected Columns:** Region, Item Type, Sales Channel, Order Priority, Order Date.
- **Steps:**
 - Used entropy and information gain to construct the tree.
 - Visualized decision tree structure.
 - Evaluated accuracy using cross-validation.

- **Objective:** Partition the data into clusters based on similarity.
- **Selected Columns:** Units Sold, Unit Price, Total Revenue, Total Profit.
- **Parameters:**
 - Number of Clusters (K): Determined using the elbow method.
 - Initialization: Used k-means++ to enhance convergence.
- **Steps:**
 - Standardized the data.
 - Applied K-Means clustering algorithm.
 - Visualized clusters and centroids.
